

Deploying Web App on ECS - Step 5: Verify and Pull Container Image from ECR

To Begin with the Lab

Summary of the Lab

In this step, the Docker image that had already been pushed to **Amazon ECR** was verified before moving to the task definition stage. The lab opened the private ECR repository, confirmed that the latest image was present, and reviewed the image details such as tag, digest, and scan findings. The image URI was then copied and saved so it could be used later in the ECS task definition. This step did not create any new resources; it only confirmed that the container image was available and ready for deployment. The saved URI became the reference that ECS would pull during the next step.

Understanding Amazon ECR Image Verification

Amazon ECR stores Docker images in a private registry so **Amazon ECS** can pull them when creating tasks. This step exists to make sure the correct image is present and that its exact URI is available before the task definition is created. Verifying the image helps avoid mistakes such as using the wrong tag or pointing ECS to the wrong repository. For example, if `cloudfolks-php-app:latest` is already stored in ECR, you can copy its URI and use that exact address in the ECS task definition so the service runs the correct version of the app.

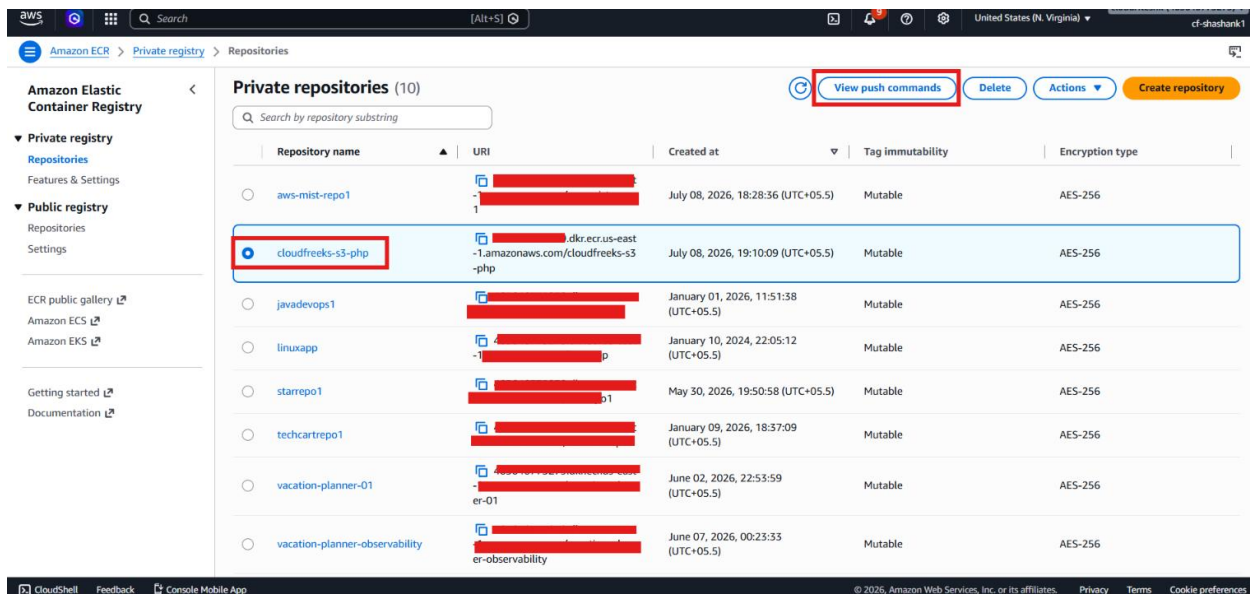

Example:

The repository contains `cloudfolks-php-app` with the latest tag. The image URI is copied from **Amazon ECR** and saved in a note file. Later, when the task definition is created, ECS uses that URI to pull the image directly from the private registry.

Lab Steps

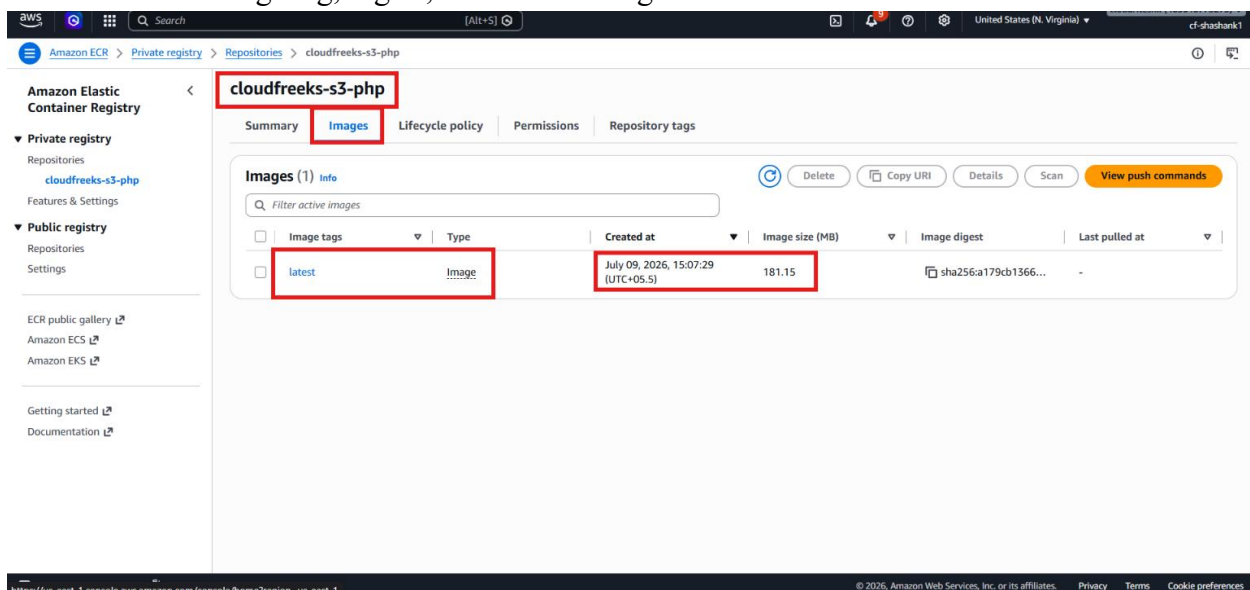

Step 1 – Open Amazon ECR

- Sign in to the **AWS Management Console**.
- Navigate to **Amazon ECR**.
- Open the private repository created earlier.

Step 2 – Verify the image

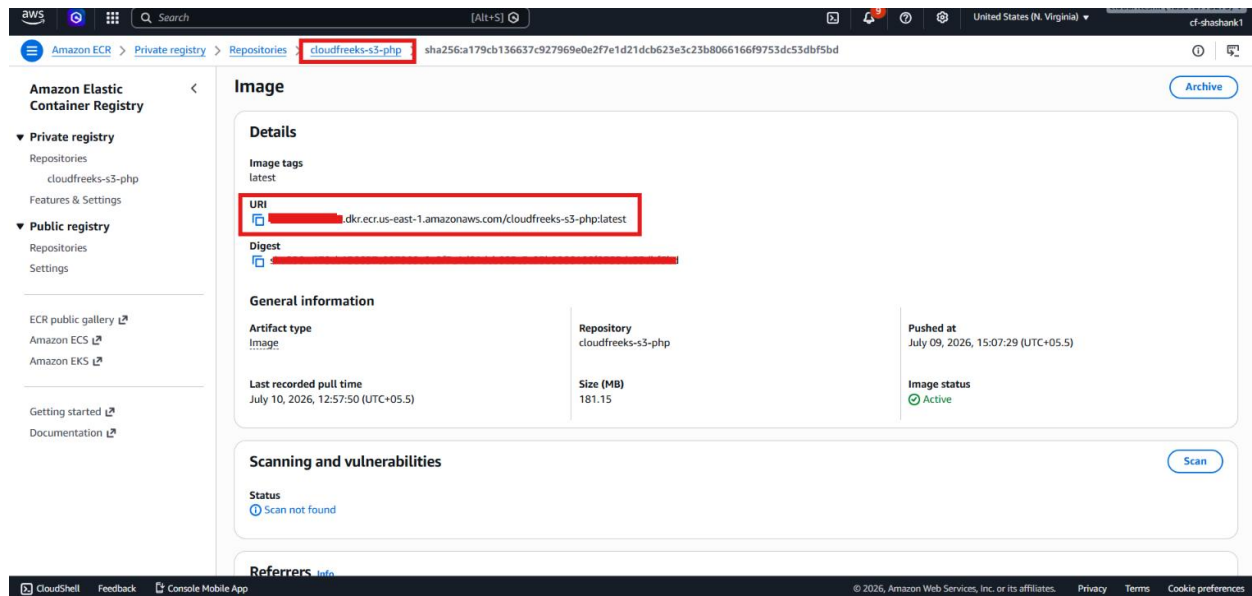

- Confirm that the latest image is listed in the repository.
- Review the image tag, digest, and scan findings.

- Check that the image is the correct one for the project.

Step 3 – Copy the image URI

- Click Copy image URI.

- Save the URI safely in a note file or text editor.
- Keep this URI ready for the ECS task definition step.

Step 4 – Prepare for the next step

- Confirm that the image is available in **Amazon ECR**.
- Confirm that the copied URI matches the application image.
- Move on to the task definition step using the saved URI.

Verification

- Verified that the private **Amazon ECR** repository contained the application image.
- Verified that the latest tag was present.
- Verified that the image details such as digest and scan findings were visible.
- Verified that the correct image URI was copied successfully.
- Verified that the image is ready to be used in the ECS task definition.
